Example 1. *Problem:*

Prove that for any integer $k > 2$, there are no positive integers x, b, and y that satisfy:

$$x^k + (b+1)^k = y^k$$

Simplified proof:

This follows directly from Fermat's Last Theorem.

Elaborated proof:

This follows directly from Fermat's Last Theorem.

Regularized proof:

Let k be an integer. Assume $k > 2$. Let x be a positive integer. Let b be a positive integer. Let y be a positive integer. The goal is to prove that there are no positive integers x, b, and y that satisfy $x^k + (b+1)^k = y^k$. We have for any integer $k > 2$, there are no positive integers x, b, and y that satisfy $x^k + (b+1)^k = y^k$ by Fermat's Last Theorem.
